

ABSTRACT

An audio storage apparatus for reproducing response message corresponding to caller information. An audio storage stores audio data such as a response message. A caller information detector detects caller information
5 incoming from a network. A message controller assigns each caller information with the response message. When calling in, the response message is reproduced on the basis of the mailbox designated by the caller and the caller information detected by the caller information detector. If there is a response message to a specific caller in an assigned mailbox, this response message is
10 reproduced. For example, by registering in the mailbox on the basis of the caller information separated into an organization and an individual person, the response message can be used selectively for the individual person and the organization.
